# Knowledge-based (re)configuration: an ASP approach 

Kostyantyn Shchekotykhin
Alpen-Adria-Universität Klagenfurt

## Outline

- More heuristics
- Class of "double" instances
- QuickPUP
- Comparison of different KRRs
- Symmetry breaking
- Portfolio solvers

## Evaluation of different KRR approaches

[Aschinger et al 2011]

## Applied KRR methods

KLAGENFURT I WIEN GRAZ

- Constraint programming: ECLiPSe-Prolog v6.0 (CSP)
- Propositional satisfiability testing: MiniSat v2.0 (SAT)
- Polynomial algorithm (DECPUP)
- Answer set programming: Clingo v3.0 (ASP)
- Integer programming:
- Cbc v2.6.2 in combination with Clp v1.13.2 (CBC) and
- Cplex v12.1 (CPLEX)

## Integer programming I

 UN|VERSIT'T- Modelled with matrixes of Boolean variables
- $s u_{i j}$ assign sensor $i$ to unit $j$ (same for zones)

$$
\begin{array}{cccc|c}
s u_{1,1} & s u_{2,1} & s u_{3,1} & \ldots & \sum \leq 2 \\
s u_{1,2} & s u_{2,2} & \ldots & \ldots & \sum \leq 2 \\
s u_{1,3} & \ldots & \ldots & \ldots & \sum \leq 2 \\
\ldots & \ldots & \ldots & \ldots & \ldots \\
\hline \sum=1 & \ldots=1 & \ldots & \ldots &
\end{array}
$$

## Integer programming II

- $u u_{i j}$ unit $i$ is a partner of the unit $j$

$$
\begin{array}{cccc|l}
1 & u u_{1,2} & u u_{1,3} & \ldots & \sum \leq \operatorname{maxPU}+1 \\
u u_{2,1} & 1 & \ldots & \ldots & \sum \operatorname{maxPU}+1 \\
u u_{3,1} & \ldots & 1 & \ldots & \sum \leq \operatorname{maxP} U+1
\end{array}
$$

- Boolean variables unitUsed ${ }_{i}$

$$
s u_{i j} \leq \text { unitUsed }_{i} \text { and } z u_{i j} \leq \text { unitUsed }_{i}
$$

- Objective function

$$
\sum_{i} \text { unitUsed }_{i}
$$

## DecPUP overview

KLAGENFURT I WIEN GRAZ

- Inspired by a hypertree decomposition algorithm [Gottob et al., 2002]
- Runs in NLOGSPACE - polynomial time
- Instance check:
- An instance has a solution if every zone or sensor has a degree less or equal to $2(\operatorname{maxP} U+1)$
- Exploits the fact that cyclic unit graphs (Mod.5) are more general solution topologies than paths
- Implements memorization of no-goods and twostep forward checking

## DecPUP idea

## DecPUP algorithm

- Given the zone-sensor graph $G=\left(V_{1}, V_{2}, E\right)$

1. Guesses two subsets of vertices $U_{1}, U_{2} \subseteq V_{1} \cup V_{2}$ such that $\left|U_{i} \cap V_{1}\right| \leq 2 \geq\left|U_{i} \cap V_{2}\right| \quad i=1 . .2$
2. Remove assigned vertices $C_{R} \leftarrow\left(V_{1} \cup V_{2}\right) \backslash$ $\left(U_{1} \cup U_{2}\right)$
Recursive function $C_{R},\left\langle U_{1}, U_{2}\right\rangle,\left\langle U_{i-1}, U_{i}\right\rangle$
3. If $C_{R}=\emptyset$ and requirements hold, then terminate
4. Guess an additional unit $U_{i+1}$ (as in steps 1 and 2)
5. Check if all neighbors of $v \in U_{i+1}$ appear in

$$
U_{i-1} \cup U_{i} \cup U_{i+1}
$$

6. Make a recursive call

## Evaluation instances

- double, double variant:
- two rows of connected rooms, each room being a zone
- variant - additional zones for each 2 connected rooms vertical to the row
- triple:
- each room being a zone
- in some cases with additional 2 or 4 zones consisting of 2-4 rooms
- grid:
- derived from real interlocking systems

[Teppan et al., 2012]

## Evaluation for maxPU = 2 |

dbl-* - double, dblv-* - double variant, tri-* - triple Cost ... number of units

## More heuristics

## "Double" instances

- A double row of connected rooms, each room being a zone
- A variant has additional zones for each 2 connected rooms vertical to the row

## Solutions for the double cases

double-80 is solved in 5 seconds (instead TO after 100 min ) just by adding definite Horn clauses to the simple program.

## Encoding extension I

KLAGENFURT I WIEN GRAZ
\% assign first zone to the first unit firstZone(Y):- $Y$ = \#min[zone(X)=X]. firstUnit(Y):- Y = \#min[unit(X)=X]. u2z(U,Z):- firstZone(Z), firstUnit(U).
adj(Z1,D,Z2) :- z2s(Z1,D), z2s(Z2,D), Z1くZ2.
\% defines a column/numeration of zones
col(Z1,D,Z2):- zone(Z1), zone(Z2), $\operatorname{adj}(Z 1, D, Z 2), \# a b s(Z 2-Z 1)>1$.

## Encoding extension II

KLAGENFURT I WIEN GRAZ
\% assign column on one unit
$u 2 z(U, Z 1):-\operatorname{col}(Z, \quad, Z 1), u 2 z(U, Z)$.
\% next column on the next unit
$u 2 z(P, Z 2):-u 2 z(U, Z), z o n e(Z 2), Z 2=Z+1$,
P \#mod 3 > 0, pu(U,P).
\% every third unit should be free
$u 2 z(X, Z 2):-u 2 z(U, Z), z o n e(Z 2), Z 2=Z+1$,
P \#mod 3 == 0, partners(U,P), partners(P,X).

## General heuristic

- For maxPU $=2$ there exists a poly-time algorithm [Aschinger et al., 2011]
- For maxPU >= 3 complexity remains unclear
- Problems of Siemens have maxPU = 4
- SAT, MIP, CP or ASP are unable to find solutions for mid- and large-size instances [Aschinger et al, 2011]
- Double works only for one class of instances
- QuickPUP is a general heuristic for solving [Teppan et al., 2012]

## QuickPUP overview I

- Recursive backtracking search algorithm
- Three main steps:

1. Order the elements (zones/sensors) in breadth-first order starting from some zone

## QuickPUP overview II

UNIVERSITAT
2. Assignment step

- Assign element to a new unit
- Else, assign the element to some used unit
- Ordering: from units with less connections to ones more connections
- Leads to many units not filled to capacity
- Greedy merging procedure for densifying and merging the units

Variation: Create new units when old units are full

- Densifying is not needed
- Might find a model with minimal number of units

## QuickPUP overview

KLAGENFURT I WIEN GRAZ
3. Use timeout to restart the search with the goal to test a different starting point

- Start from step 1 and select the next zone to build the ordering
- Restart Do 1. and 2. for every zone or until a solution is found
- The algorithm continues until a solution is found

## Experimental Setup

- Restart in 1 second
- QuickPup (new unit first)
- QuickPup* (old units first)
- QP and QP* were implemented in Java 1.5.
- Timeout $=600$ secs

## Results

## IUCAP=2, UCAP=2

## Results for real cases: QP << 1 sec - ASP up to 17 minutes

## Portfolio solvers

## Portfolio solvers I

 UNIVERSITNT- Modern solvers
- are highly configurable
- implement different heuristics and tie breaking strategies
- Which solver/solver configuration works best for my problem?
- Portfolio solvers:
- Claspfolio http://potassco.sourceforge.net/
- ME-ASP https://www.mat.unical.it/ricca/me-asp/

## Portfolio solvers: an overview I

- Given a representative set of problems and their instances
- Extract features characterizing the problem instances (>100 features)
- Solve each instance with different configurations/solvers
- Apply machine learning to find "empirical hardness" of the problem instance
- Statistical model predicting runtime of different configurations/solvers

## Portfolio solvers: an overview II

- Given a new program
- extracts a set of features used to classify the program
- find the best configuration/solver for the instance
- Claspfolio was used for solving double cases which turned out to be the hardest cases for all programs

## Claspfolio, evaluation details

- Input: the double case double-20 and simple program
- Output: chosen solver configuration (set of options):
--heu=VSIDS --del=3,1.1,1000
--restarts=100,1.5,20000 --local-restarts
- VSIDS - Variable State Independent Decaying Sum
- del - fixes the size and growth factor of the dynamic nogood database
- restarts - parameterizes a restart policy
- local restarts - exploits local restarts

## Symmetry breaking in ASP

## Symmetry breaking I

- Symmetry: one solution can be obtained from the other by renaming constants
- House problem (e.g. renaming of cabinets) t2c $(1,10), \mathrm{t} 2 \mathrm{c}(2,11)$-> t2c $(1,11), \mathrm{t} 2 \mathrm{c}(2,10)$
- Same for PUP (renaming of units)
- Simple symmetry breaking
- PUP: assign first sensor to the first unit and the second one to a unit in the first half of the cycle
- House: assign things with smaller ids to cabinets with smaller ids

## Symmetry breaking II

- Problems:
- Finding symmetries is hard
- Blocking them is even harder
- Do all instances have the same symmetries?
- Is automatic detection and blocking of symmetries possible?

## Example: House problem

cabinet(10..12).
thing(1..3).
$\{c 2 t(X, Y): c a b i n e t(X)\} 1$ :- thing(Y).
placed(T) :- c2t(X,T).
:- thing(X), not placed(X).

27 Models:
c2t(10,3) c2t(10,2) c2t(10,1)
c2t $(12,3)$ c2t $(12,2) \operatorname{c2t}(12,1)$

## Symmetry breaking I

KLAGENFURT I WIEN GRAZ
Three types of symmetry breaking for SAT:

- variable $(A, B)$,
- value $(A, \neg A)$ and
- variable-value $(A, \neg B)$
where $A$ and $B$ are propositional symbols, and $(A, B)$ is a permutation that replaces $A$ in all clauses of a CNF with $B$ and vice versa

## Symmetry breaking II

klagenfurt I wien graz

- Permutations in a CNF are generators of symmetric solutions
- Identification of permutations can be reduced to the colored graph automorphism problem
- Automorphism is, in some sense, a way of mapping the object to itself while preserving all of its structure (coloring), i.e. a symmetry of a mathematical object
- Algorithms like saucy, nauty or bliss can be used to find automorphims of a colored graph

## Grounded program

cabinet(10). cabinet(11). cabinet(12). thing(1). thing(2). thing(3). \#count\{c2t(12,3), c2t(11,3), c2t(10,3)\}1. \#count\{c2t(12,2),c2t(11,2),c2t(10,2)\}1. \#count\{c2t(12,1), c2t(11,1),c2t(10,1)\}1. placed(1):-c2t(10,1).
placed(2):-c2t(11,2).
:-not placed(2).
:-not placed(1).

## Graph coloring I

\#count $\{\operatorname{c} 2 t(12,3), \operatorname{c} 2 t(11,3), \operatorname{c} 2 t(10,3)\} 1$.

## Graph coloring II

- placed(1):-c2t(10,1).

- : -not placed(1).

## Symmetry breaking rules

- SBASS was queried to find 6 permutation sets corresponding to automorphisms of the colored graph [Drescher et al., 2011]

11212019
$:-\operatorname{not} c 2 t(10,1), c 2 t(11,1)$.

```
(18 19)
1 1 2 1 19 18
:- not c2t(11,1), c2t(12,1).
```

- Other four constraints are defined for the things 2 and 3

## Breaking the symmetries

KLAGENFURT I WIEN GRAZ

- Grounded program is extended with SBASS SB constraints
- Clasp returns the only model:
cabinet(10) cabinet(11) cabinet(12)
thing(1) thing(2) thing(3)
c2t $(10,3)$ c2t $(10,2)$ c2t $(10,1)$
placed(1) placed(2) placed(3)

## SBASS architecture

## Evaluation

- Limit - number of computed generators - TO - timeout 600 seconds

| Instance | Optimum | No SBASS | SBASS, default | SBASS, limit=5 | SBASS, limit=20 |

## Some good news :-)

## Problem instance 1

## Solution was unknown.

## Solution of instance 1

unit2zone $(35,64)$.
unit2sensor $(1,32)$.
partnerunits $(1,35)$ partnerunits( 35,1 )

Time:
13 seconds (simple + parameter learning)

## Problem instance 2

## Solution of instance 2

unit2zone (13, 79).
unit2sensor $(47,102)$.
partnerunits $(13,47)$. partnerunits $(47,13)$.
...

Time: 25 seconds (simple + parameter learning)
