Outline of PART I

Introduction to Decomposition Methods

Free Decompositions

Applications of Tree Decompositions

Inherent Problem Complexity

- Problems decidable or undecidable.
- We concentrate on decidable problems here.
- A problem is as complex as the best possible algorithm which solves it.

Inherent Problem Complexity

• Problems decidable or undecidable.

Time Complexity

- We concentrate on decidable problems here.
- A problem is as complex as the best possible algorithm which solves it.

Approaches for Solving Hard Problems

- NP-complete problems often occur in practice.
- They must be solved by acceptable methods.
- Three approaches:
 - Randomized local search
 - Approximation
 - Identification of easy (=polynomial) subclasses.

Approaches for Solving Hard Problems

- ${\ensuremath{\bullet}}$ NP-complete problems often occur in practice.
- They must be solved by acceptable methods.
- Three approaches:
 - Randomized local search
 - Approximation
 - Identification of easy (=polynomial) subclasses.

Identification of Polynomial Subclasses

- High complexity often arises in "rare" worst case instances
- Worst case instances exhibit intricate structures
- In practice, many input instances have simple structures
- Therefore, our goal is to
 - Define polynomially solvable subclasses (possibly, the largest ones)
 - Prove that membership testing is tractable for these classes
 - Develop efficient algorithms for instances in these classes

Graph and Hypergraph Decompositions

- The evil in Computer science is hidden in (vicious) cycles.
- We need to get them under control!
- <u>Decompositions</u>: Tree-Decomposition, path decompositions, hypertree decompositions,...
 Exploit bounded degree of cyclicity.

Problems with a Graph Structure

• With graph-based problems, high complexity is mostly due to *cyclicity*.

Problems restricted to acyclic graphs are often trivially solvable (\rightarrow 3COL).

 Moreover, many graph problems are polynomially solvable if restricted to instances of low cyclicity.

Problems with a Graph Structure

 With graph-based problems, high complexity is mostly due to *cyclicity*.
 Problems restricted to *acyclic* graphs are often

trivially solvable (\rightarrow 3COL).

 Moreover, many graph problems are polynomially solvable if restricted to instances of *low cyclicity*.

How can we measure the degree of cyclicity?

How much "cyclicity" in this graph?

• Suggest a measure of distance from an acyclic graph

Feedback vertex set

Set of vertices whose deletion makes the graph acyclic

FVN: Properties

JCAI-13

Feedback vertex number

Min. number of vertices I need to eliminate to make the graph acyclic

- Is this really a good measure for the "degree of acyclicity" ?
- Pro: For fixed k we can check efficiently whether fwn(G) ≤ k
 - What does it mean *efficiently* when parameter k is fixed?

But...

 In many problems there exists some part of the input that are quite small in practical applications

- Natural parameters
- Many NP-hard problems become easy if we fix such parameters (or we assume they are below some fixed threshold)
- Positive examples: k-vertex cover, k-feedback vertex set, k-clique, ...
- Negative examples: k-coloring, k-CNF, …

W[1]-hard problems: k-clique

k-clique is hard w.r.t. fixed parameter complexity!

INPUT: A graph *G*=(*V*,*E*) **PARAMETER:** Natural number *k*

• Does G have a clique over k vertices?

FPT Tractability of Feedback Vertex Set

INPUT: A graph G=(V,E)

PARAMETER: Natural number k

- Does G has a feedback vertex set of k vertices?
- Naïve algorithm: O(n^{k+1}) Not good!
- Solvable in O((2k+1)^kn²) [Downey and Fellows '92]
- A practical randomized algorithm runs in time: $O(4^k kn)$ [Becker et al 2000]

Feedback Vertex Set: troubles

Feedback vertex number

Min. number of vertices I need to eliminate to make the graph acyclic

Peedback <u>edge</u> number → same problem.

Any idea for further techniques?

Yes! A tree of clusters (subproblems)

- Well known graph properties:
 - A biconnected component is a maximal subgraph that remains connected after deleting any single vertex
 - In any graph, its biconnected components form a tree

Maximum size of biconnected components

Pro: Actually bcw(G) can be computed in linear time

Drawbacks of BiComp

Maximum size of biconnected components

Pro: Actually bcw(G) can be computed in linear time

Con: Adding a single edge may have tremendous effects to bcw(G)

Drawbacks of BiComp

Maximum size of biconnected components

Con: Adding a single edge may have tremendous effects to bcw(G)

Can we do better?

Hint:

why should clusters of vertices be of this limited kind?

- Use arbitrary (possibly small) sets of vertices!
 - How can we arrange them in some tree-shape?
 - What is the key property of tree-like structures (in most applications)?

Can we do better?

Hint:

ntroduction to Decomposition Methods

Tree Decompositions

Applications of Tree Decompositions

Use of Tree Decompositions

1. Prove Tractability of bounded-width instances

- a) Genuine tractability: O(nf(w))-bounds
- b) Fixed-Parameter tractability: f(w)*O(nk)

2. Tool for proving general tractability

- a) Prove tractability for both large & small width
- b) Prove all yes-instances to have small width

Use of Tree Decompositions

1. Prove Tractability of bounded-width instances

- a) Genuine tractability: O(n^{f(w)})-bounds constraint satisfaction = conjunctive database queries
- b) Fixed-Parameter tractability: f(w)*O(n^k) multicut problem

2. Tool for proving general tractability

- a) Prove tractability for both large & small width finding even cycles in graphs – ESO over graphs
- b) Prove all yes-instances to have small width the Partner Unit Problem

Use of Tree Decompositions

- JCAI-13

An important Metatheorem

Courcelle's Theorem [1987]

Let P be a problem on graphs that can be formulated in **Monadic Second Order Logic** (MSO).

Then P can be solved in liner time on graphs of bounded treewidth

An important Metatheorem

JCAI-13

Courcelle's Theorem [1987]

Let P be a problem on graphs that can be formulated in **Monadic Second Order Logic** (MSO).

Then P can be solved in liner time on graphs of bounded treewidth

- Theorem. (Fagin): Every NP-property over graphs can be represented by an existential formula of Second Order Logic. NP=ESO
- Monadic SO (MSO): Subclass of SO, only set variables, but no relation variables of higher arity.
 3-colorability ∈ MSO.

Three Colorability in MSO

JCAI-13

 $(\exists R, G, B)$ [

 $\begin{array}{l} (\forall x \left(R(x) \lor G(x) \lor B(x) \right)) \\ \land \quad (\forall x (R(x) \Rightarrow (\neg G(x) \land \neg B(x)))) \end{array}$

- ∧ ... ∧ ...
- $\land \quad (\forall x, y(E(x,y) \Rightarrow (R(x) \Rightarrow (G(x) \lor B(y)))))$
- $\land \quad (\forall x, y(E(x, y) \Rightarrow (G(x) \Rightarrow (R(x) \lor B(y)))))$
- $\land \quad (\forall x, y(E(x, y) \Rightarrow (B(x) \Rightarrow (R(x) \lor G(y)))))]$

Master Theorems for Treewidth

JJCAI-13

Courcelle's Theorem: Problems expressible in MSO₂ are solvable in linear time on structures of bounded treewidth

...and in LOGSPACE [Elberfeld, Jacoby, Tantau]

Example – Graph Coloring

 $\exists P \ \forall x \forall y : (E(x,y) \rightarrow (P(x) \neq P(y))$

Master Theorems for Treewidth

Arnborg, Lagergren, Seese '91:

Optimization version of Courcelle's Theorem:

Finding an optimal set P such that $G \models \Phi(P)$ is FP-linear over inputs G of bounded treewidth.

Example:

Given a graph G=(V,E)

Find a *smallest* P such that $\forall x \forall y : (E(x,y) \rightarrow (P(x) \neq P(y))$

Unrestricted Vertex Multicut Problems

Results

[Guo et al. 06] UVMC FPT if |S|, |C| and tree-width fixed

[G. & Tien Lee] UVMC FPT if overall structure has bounded tw. using master theorem by Arnborg, Lagergren and Seese.

Unrestricted Vertex Multicut Problems

PROOF

Definition 8. On structures $\mathcal{A} = (V, E, H)$ as above, let *connects*(S, x, y) be defined as follows: $S(x) \land S(y) \land \forall P\Big((P(x) \land \neg P(y)) \rightarrow (\exists v \exists w (S(v) \land S(w) \land P(v) \land \neg P(w) \land E(v, w)))\Big).$

 $uvmc(X) \hspace{.1in} \equiv \hspace{.1in} \forall x \hspace{.05in} \forall y \left(\hspace{.05in} H(x,y) \rightarrow \forall S \big(\operatorname{connects}(S,x,y) \rightarrow \exists v(X(v) \wedge S(v)) \big) \right)$

Minimize X in uvmc

X intersects each set that connects \boldsymbol{x} and \boldsymbol{y}

Use of Tree Decompositions

JCAI-13

- 1. Prove Tractability of bounded-width instances
 - a) Genuine tractability: $O(n^{f(w)})\mbox{-bounds}$
 - b) Fixed-Parameter tractability: f(w)*O(n^k)

2. Tool for proving general tractability

a) Prove tractability for both large & small width

b) Prove all yes-instances to have small width

The Generalized Even Cycle Problem

INPUT: A graph G, a constant k.

QUESTION: Decide whether G has a cycle of length 0 (mod k)

In the past century, this was an open problem for a long time.

Carsten Thomassen in 1988 proved it polynomial for *all graphs* using treewidth as a tool.

Long Term Research Programme

Determine the complexity of SO fragments over finite structures.

Finite structures: words (strings), graphs, relational databases

Known: SO=PH; ESO = NP

Which SO-fragments can be evaluated in polynomial time?

Which SO-fragments express regular languages on strings ?

More modestly: What about prefix classes?

A "simple" Facility Placement Problem

If a printer is not present in a room, then one should be available in an adjacent room.

No room with a printer should be a meeting room.

Every room is at most 5 rooms distant from a meeting room.

Simplest Form

Given an office layout as a graph, decide whether the facility placement constraints are satisfiable.

∃ P ∃ M ... ∀x ∃ y ((P(x) ∨ E(x,y) & P(y)) & ...

[...]

Observe that this is an E₁*ae formula

This leads to the questions:

Are formulas of the type E_1^* are or even E^* are polynomially verifiable over graphs?

What about other fragments of ESO or SO?

Simplest Form

This motivates the following question:

Can formulas in classes such as $E_2(ae_2)$ or even ESO(e*ae*) be evaluated in polynomial time over strings ?

More generally:

Which ESO-fragments admit polynomial-time model checking over strings ?

A similar, even more important question can be asked for graphs and general finite structures:

Which ESO-fragments admit polynomial-time model checking over graphs or arbitrary finite structures?

The Saturation Problem

Relating E_1^*ae to the Saturation Problem

 $\exists P_1, P_2 \forall x \exists y$ $[(E(x, y) \land P_1(x) \land P_2(x) \land P_1(y) \land \neg P_2(y)) \lor$ $(E(x, y) \land P_1(x) \land \neg P_2(x) \land \neg P_1(y) \land \neg P_2(y)) \lor$ $(\neg E(x, y) \land \neg P_1(x) \land \neg P_2(x) \land P_1(y) \land P_2(y))]$

Use of Tree Decompositions

JCAI-13

- 1. Prove Tractability of bounded-width instances
 - a) Genuine tractability: $O(n^{f(w)})\text{-bounds}$
 - b) Fixed-Parameter tractability: f(w)*O(n^k)

2. Tool for proving general tractability

a) Prove tractability for both large & small width

b) Prove all yes-instances to have small width

Partner Units Scenario

- Track People in Buildings
- Sensors on Doors, Rooms Grouped into Zones

Partner Units Solution

 Assigning Sensors and Zones to Control Units

 Respect Adjacency Constraints

The Partner-Unit Problem

Bipartite graph G=(V,E) V=Va∪Vb; Va= {a1,...,ar}, Vb={b1,...,bs}, E: edges btw. Va and Vb

The Partner-Unit Problem

Replace connections by connections to units

ai 🔵 🗌 🔵 bj

The Partner-Unit Problem

Bipartite graph G=(V,E) V=Va \cup Vb; Va= {a1,...,ar}, Vb={b1,...,bs}, E: edges btw. Va and Vb

Replace connections by connections to units ai ______ bj

OR

The Partner-Unit Problem

Bipartite graph G=(V,E) V=Va \cup Vb; Va= {a1,...,ar}, Vb={b1,...,bs}, E: edges btw. Va and Vb

The Partner-Unit Problem

•Each ai or bi is connected to exactly 1 unit. •Each unit connected to:

- at most 2 other units,

- at most 2 elements from Va,

- at most 2 elements from Vb, •If ai connected to bj in G,

then dist(ai,bi)≤3 in G*

G

A No-Instance of Partner-Unit

Assume one node a is connected to 7 nodes b1,...,b7 in G. Then instance G is unsolvable.

Thus, no vertex can have more than 6 neighbours in G.

The PU Problem(s)

- PU DECISION PROBLEM (PUDP): Given G, is there a G* satisfying the constraints? (Number of units irrelevant.)
- PU SEARCH PROBLEM (PUSP) Given G, find a suitable G* whenever possible.
- PU OPTIMIZATION PROBLEM (PUOP) Given G, find a suitable G* with minimum number of units |U| (whenever possible).

PUDP

IJCAI-13

ASSUMPTION: G is connected.

- Note: This assumption can be made wlog, because the PUDP can be otherwise decomposed into a conjunction of independent PUDPs, one for each component.
- **Lemma 1:** If G is connected and solvable, then there exists a solution G^* in which the unit-graph UG=G^{*}[U] is connected.

Topology of the Unit-Graph

Lemma 2: If G is connected and solvable, then there exists a solution G* whose unit graph is a cycle.

Note: We still don't know |U|, but we may just try all cycles of length max(|Va|,|Vb|)/2 to length |Va|+|Vb|. There are only linearly many! (Guessable in logspace)

JCAI-13

Theorem:

Assume G is solvable through solution G^* with $\,|\mathsf{U}|\!=\!\mathsf{n}$ and having

unit function f . Then:

- (1) $pw(G) \le 11$
- (2) $tw(G) \le 5$
- (3) There is a path decomposition T=(W,A) that can be locally check to witnss PUDP solution G*

Example

JJCAI-13

Note: We cannot do better, thus the bound 11 is actually tight!

Note: Other examples show, we cannot do better, thus the bound 5 is actually tight

Example for lower bound 5

... and this G is actually solvable:

Theorem : PUDP is in polynomial time and is solvable by dynamic programming techniques.

Case N>2

For constant N totally open. Could well be NP-hard. In fact, Unit Graph does not need to have bounded treewidth!

If N is not-constant, then NP-complete:

For Siemens, it seems that very small values of N are relevant.

Populating datawarehouses

Problems on Electric Circuits

A problem from Nasa

Part of relations for the Nasa problem

680 constraints
 530 constraints

579 variables

Configuration problems (Renault example)

- Renault Megane configuration [Amilhastre, Fargier, Marquis AIJ, 2002] Used in CSP competitions and as a benchmark problem
- Variables encode type of engine, country, options like air cooling, etc.
- 99 variables with domains ranging from 2 to 43.
- 858 constraints, which can be compressed to 113 constraints.
- The maximum arity is 10 (hyperedge cardinality/size of constraint scopes)
- Represented as extensive relations, the 113 constraints comprise about 200 000 tuples
- 2.84 × 10¹² solutions.

Hypergraphs vs Graphs

An acyclic hypergraph

Its cyclic primal graph

JCAI-13

Deciding Hypergraph Acyclicity

Can be done in linear time by <u>GYO-Reduction</u>

[Yu and Özsoyoğlu, IEEE Compsac'79; see also Graham, Tech Rep'79]

Input: Hypergraph H

 (1) Eliminate vertices that are contained in at most one hyperedge (2) Eliminate hyperedges that are smaller at contained in attent hyperedge
--

Proof: Easy by considering leaves of join tree

1

Tree decompositions as Join trees

- Tree decomposition as a way of clustering vertices to obtain a join tree (acyclic hypergraph)
- Implicitly defines an equivalent acyclic instance

Acyclic instance

From graphs to acyclic hypergraphs

- The "degree of cyclicity" is the treewidth (maximum number of vertices in a cluster -1)
- In this example, the treewidth is 2
- That's ok! We started with a cyclic graph...

Equivalent acyclic instance

Not good for hypergraph-based problems

However, its treewidth is 2! (similar troubles for all graph representations)

Input: acyclic hypergraph

Primal graph

width-2 tree decomposition

A different notion of "width"

- Exploit the fact that a single hyperedge *covers* many vertices
- Degree of cyclicity: maximum number of hyperedges needed to cover every cluster

Input: acyclic instance

One hyperedge covers each cluster: width 1

Generalizing acyclicity and treewidth

- Tree decomposition as a way of clustering vertices to obtain a join tree (acyclic hypergraph)
- Implicitly defines an equivalent acyclic instance
- Width of a decomposition: maximum number of hyperedges needed to cover each bag of the tree decomposition
- Generalized Hypertree Width (ghw): minimum width over all possible decompositions [Gottlob, Leone, Scarcello, JCSS'03]
 also known as (acyclic) cover width
- Generalizes both acyclicity and treewidth:
 - Acyclic hypergraphs are precisely those having ghw = 1
 - The "covering power" of a hyperedge is always greater than the covering power of a vertex (used in the treewidth)

Computational Question

 Can we determine in polynomial time whether ghw(H) < k for constant k ?

Computational Question

• Can we determine in polynomial time whether ghw(H) < k for constant k ?

Bad news: <u>ghw(H) < 4?</u> NP-complete

[Gottlob, Miklós, and Schwentick, J.ACM'09]

Hypertree Decomposition (HTD)

HTD = Generalized HTD +Special Condition [Gottlob, Leone, Scarcello, PODS'99; JCSS'02] Each variable not used $\mathbf{j}(\mathbf{J},\mathbf{X},\mathbf{Y},\mathbf{X}^{\prime},\mathbf{Y}^{\prime})$ at some vertex v a(S,X,X',C,F), b(S,Y,Y',C',F')**j**(_,X,Y,_,_), **c**(C,C',Z) j(XY, X', Y'), f(F,F',Z')d(X,Z)e(Y,Z) $g(X^{\prime},\!Z^{\prime}),\,f\!(F\!,_,\!Z^{\prime})$ h(Y',Z')Does not appear in $\mathbf{p}(\mathbf{B},\mathbf{X}',\mathbf{F})$ q(B',X',F) the subtrees rooted at v

Special Condition

Positive Results on Hypertree Decompositions

- For fixed k, deciding whether hw(Q) ≤ k is in polynomial time (LOGCFL)
- Computing hypertree decompositions is feasible in polynomial time (for fixed k).

But: FP-intractable wrt k: W[2]-hard.

Marshals block hyperedges

Game Characterization: Robber and Marshals

- A robber and *k* marshals play the game on a hypergraph
- The marshals have to capture the robber
- The robber tries to elude her capture, by running arbitrarily fast on the vertices of the hypergraph

Robbers and Marshals: The Rules

IJCAI-1

- Each marshal stays on an edge of the hypergraph and controls all of its vertices at once
- The robber can go from a vertex to another vertex running along the edges, but she cannot pass through vertices controlled by some marshal
- The marshals win the game if they are able to monotonically shrink the moving space of the robber, and thus eventually capture her
- Consequently, the robber wins if she can go back to some vertex previously controlled by marshals

R&M Game and Hypertree Width

JCAI-13

Let *H* be a hypergraph.

- **Theorem**: *H* has hypertree width $\leq k$ if and only if *k* marshals have a winning strategy on *H*.
- **Corollary**: *H* is acyclic if and only if one marshal has a winning strategy on *H*.
- Winning strategies on H correspond to hypertree decompositions of H and vice versa.

[Gottlob, Leone, Scarcello, PODS'01, JCSS'03]

A Useful Tool: Alternating Turing Machines

- Generalization of non-deterministic Turing machines
- There are two special states: \$ and "
- Acceptation: Computation tree
- ALOGSPACE = PTIME

Co

ATMs and LOGCFL

- LOGCFL: class of problems/languages that are logspace-reducible to a CFL
- Admit efficient parallel algorithms

 $AC_0 \subseteq NL \subseteq {\color{black}{\mathsf{LOGCFL}}} = SAC_1 \subseteq AC_1 \subseteq NC_2 \subseteq \cdots \subseteq NC = AC \subseteq P \subseteq NP$

Characterization of LOGCFL [Ruzzo '80]: LOGCFL = Class of all problems solvable with a logspace ATM with polynomial tree-size

Coming back to Marshals...

A polynomial algorithm: ALOGSPACE

Beyond Tree Decompositions

Applications to Databases and CSPs

Structural and Consistency Properties

Some hypergraph based problems

HOM: The homomorphism problem

BCQ: Boolean conjunctive query evaluation

CSP: Constraint satisfaction problem

Important problems in different areas. All these problems are hypergraph based.

[e.g., Kolaitis & Vardi, JCSS'98]

The Homomorphism Problem

- Given two relational structures
 - $\mathbb{A} = (U, R_1, R_2, \dots, R_k)$ $\mathbb{B} = (V, S_1, S_2, \dots, S_k)$
- ullet Decide whether there exists a *homomorphism* **h** from \mathbb{A} to \mathbb{B}

$$h: U \longrightarrow V$$

such that $\forall \mathbf{x}, \forall i$
 $\mathbf{x} \in R_i \implies h(\mathbf{x}) \in S_i$

Example: graph colorability

Complexity: HOM is NP-complete

(well-known, independently proved in various contexts)

Membership: Obvious, guess h.

Hardness: Transformation from 3COL.

Graph 3-colourable iff HOM(A,B) yes-instance.

Conjunctive Database Queries

DATABASE:

Endomorphisms and cores

- Sometimes the two structures coincide
- Core: minimal substructure to which there is an endomorphism
- Cores are isomorphic to each other

Endomorphisms and cores

- Sometimes the two structures coincide
- Core: minimal substructure to which there is an endomorphism
- Cores are isomorphic to each other

Endomorphisms and cores

- Sometimes the two structures coincide
- Core: minimal substructure to which there is an endomorphism
- Cores are isomorphic to each other

Cores and equivalent instances

- Can be used to simplify problems
- There is a homomorphism from **A** to **B** if and only if there is a homomorphism from a/any core of **A** to **B**
- Sometimes terrific simplifications:

• This undirected grid is equivalent to a single edge. That is, it is equivalent to an acyclic instance!

Structurally Restricted CSPs

[Yannakakis, VLDB'81]

[Gottlob, Leone, Scarcello, J.ACM'00]

A Polynomial-time Algorithm

HOM: The homomorphism problem

BCQ: Boolean conjunctive query evaluation

CSP: Constraint satisfaction problem

Yannakakis's Algorithm (Acyclic structures):

 Dynamic Programming over a Join Tree, where each vertex contains the relation associated with the corresponding hyperedge

 Therefore, if there are more constraints over the same relation, it may occur (as a copy) at different vertices

«Answering» Acyclic Instances

- HOM: The homomorphism problem
- BCQ: Boolean conjunctive query evaluation
- CSP: Constraint satisfaction problem

Yannakakis's Algorithm (Acyclic structures): Dynamic Programming over a Join Tree

Solutions can be computed by adding a top-down phase to Yannakakis' algorithm for acyclic instances

Computing the result (Acyclic)

- The result size can be exponential (even in the acyclic case).
- Even when the result is of polynomial size, it is in general hard to compute.
- In case of acyclic instances, the result can be computed in time polynomial in the result size (and with polynomial delay: first solution, if any, in polynomial time, and each subsequent solution within polynomial time from the previous one).
- This will remain true for the subsequent generalizations of acyclicity.
- Add a top-down phase to Yannakakis' algorithm for acyclic instances, thus obtaining a full reducer, and join the partial results (or perform a backtrack free visit)

Decomposition Methods

Decomposition Methods

Hypertrees for Databases

JCAI-13

Inside PostgreSQL

Large width example: Nasa problem

Part of relations for the Nasa problem

680 relations579 variables

Nasa problem: Hypertree

Further Structural Methods

- Many proposals in the literature, besides (generalized) hypertree width (see [Gottlob, Leone, Scarcello. Art. Int.'00])
- For the binary case, the method based on tree decompositions (first proposed as heuristics in [Dechter and Pearl. Art.Int.'88 and Art.Int.'89]) is the most powerful [Grohe. J.ACM'07]
- Let us recall some recent proposals for the general (non-binary) case:
 - Fractional hypertree width [Grohe and Marx. SODA'06]
 - Spread-cut decompositions [Cohen, Jeavons, and Gyssens. J.CSS'08]
 - Component Decompositions [Gottlob,Miklòs,and Schwentick. J.ACM'09]
 - Greedy tree projections [Greco and Scarcello, PODS'10, ArXiv'12]
- Computing a width-k decomposition is in PTIME for all of them (for any fixed k>0).
- If we relax the above requirement, we can consider fixed-parameter tractable methods. If the size of the hypergraph structure is the fixed parameter, the most powerful is the Submodular width [Marx. STOC'10]

Heuristics for large width instances (CSPs)

1. Computing decompositions

Heuristics to get variants of (hyper)tree decompositions

- 2. Evaluating instances
 - Computing all solutions of the subproblems involved at each node may be prohibitive
 - Memory explosion
- Solution: combine with other techniques. E.g., in CSPs,
 - use (hyper)tree decompositions for bounding the search space [Otten and Dechter. UAI'08]
 - use (hyper)tree decompositions for improving the performance of consistency algorithms (hence, speeding-up propagations) [Karakashian, Woodward, and Choueiry. AAAI'13]
 - ...

Alternative constraint encodings

- Some tractability results hold only on constraint encodings where allowed tuples are listed as finite relations
- Alternative encodings make sense
- For instance,
 - constraint satisfaction with succinctly specified relations [Chen and Grohe. J.CSS'10]
 - see also [Cohen, Green, and Houghton. CP'09]

Outline of PART II

Beyond Tree Decompositions

Applications to Databases and CSPs

Structural and Consistency Properties

Local (pairwise) consistency

- For every relation/constraint: each tuple matches some tuple in every other relation
- Can be enforced in polynomial time: take the join of all pairs of relations/constraints until a fixpoint is reached, or some relation becomes empty
 - See [Beeri, Fagin, Maier, and Yannakakis. J.ACM'83] or [Janssen, Jégou, Nougier, and Vilarem. IEEE WS Tools for Al'89],

Enforcing pairwise consistency

Enforcing pairwise consistency

Enforcing pairwise consistency

- Further steps are useless, because the instance is now locally consistent
- On acyclic instances, same result as Yannakakis' algorithm on the join tree!

Easy on Acyclic Instances

• Computing a join tree (in linear time, and logspace-complete [GLS'98+ SL=L]) may be viewed as a clever way to enforce pairwise consistency

- Cost for the computation of the locally consistent instance: $O(m n^2 \log n)$ vs $O(m n \log n)$
- N.B. n is the (maximum) number of tuples in a relation and may be very large (esp. in database applications)

Global and pairwise Consistency

- Yannakakis' algorithm actually solves acyclic instances because of their following crucial property:
 - Local (pairwise) consistency → Global consistency [Beeri, Fagin, Maier, and Yannakakis. J.ACM'83]
 - Global consistency: Every tuple in each relation can be extended to a full (global) solution
 - In particular, if all relations/constraints are pairwise consistent, then the result is not empty
- Not true in the general case: $ans:-a(X,Y) \land b(Y,Z) \land c(Z,X)$

Consistency in Databases and CSPs

 Huge number of works in the database and constraint satisfaction literature about different kinds (and levels) of consistencies
 (e.g., recall the seminal paper [Mackworth. Art. Int., 1977]

or [Beeri, Fagin, Maier, and Yannakakis. J.ACM'83], [Dechter. Art. Int., 1992], and [Dechter and van Beek. TCS'97])

- Most theoretical papers in the database community
- Also practical papers in the constraint satisfaction community:
 - Local consistencies are crucial for filtering domains and constraints
 - Allow tremendous speed-up in constraint solvers
 - Sometimes allow backtrack-free computations

Global consistency in Databases and CSPs

- Global consistency (GC): Every tuple in each relation can be extended to a full (global) solution [Beeri, Fagin, Maier, and Yannakakis. J.ACM'83]
- For instances with m constraints, it is also known as
 - m-wise consistency [Gyssens. TODS'86]
 - relational (i;m)-consistency [Dechter and van Beek. TCS'97]
 - R(*,m)C [Karakashian, Woodward, Reeson, Choueiry and
 - Bessiere. AAAI'10]
 - ...
- Remark:
 - In the CSP literature, "global consistent network" sometimes means "strongly n-consistent network", which is a different notion (see, e.g., [Constraint Processing, Dechter, 2003]).

On the desirability of Global Consistency

- If an instance is globally consistent, we can immediately read partial solutions from the constraint/database relations
- full solutions are often computed efficiently
- can be exploited in heuristics by constraint solvers. For a very recent example, see
 - [Karakashian, Woodward, and Choueiry. AAAI'13]: enforce global consistency on groups of subproblems (tree-like arranged) for bolstering propagations

When pairwise consistency entails GC

- We have seen that it happens in acyclic instances...
- Is it the case that this condition is also necessary?
- What is the real power of local (pairwise) consistency? i.e., relational arc-consistency (more precisely, arc-consistency on the dual graph) Also known as
 - 2-wise consistency [Gyssens. TODS'86],
 - R(*,2)C [Karakashian, Woodward, Reeson, Choueiry and Bessiere. AAAI'10]

When pairwise consistency entails GC

- The classical result that this is also necessary [Beeri, Fagin, Maier, and Yannakakis. J.ACM'83] actually holds only if relations cannot be used in more than one constraint/query atoms
- In fact, it works even on some cyclic instances
- We now have a precise structural characterization of the instances where local consistency entails global consistency
 - it applies to the binary case, too
 - it applies to the more general case where pairwise consistency is enforced between each pair of arbitrary defined subproblems (see appendix)!

[Greco and Scarcello. PODS'10]

The Power of Pairwise Consistency

- Let us describe when local (pairwise) consistency (LC) entails global consistency (GC), on the basis of the constraint structure
- That is, we describe the condition such that:
 whenever it holds, LC entails GC for every possible CSP instance (i.e., no matter on the constraint relations)
 - ${\ensuremath{\, \bullet }}$ if it does not hold, there exists an instance where LC fails
- For binary (or fixed arity) instances: if we are interested only in the decision problem (is the CSP satisfiable?) than this condition is the existence of an acyclic core [Atserias, Bulatov, and Dalmau. ICALP'07]

The Power of Pairwise Consistency

 Does pairwise consistency entail global consistency in this case?

The Power of Pairwise Consistency

- Does pairwise consistency entail global consistency in this case?
- Yes! No matter of the tuples in the constraint relation e
- Every constraint is a core of the instance

The Power of Pairwise Consistency

- Does pairwise consistency entail global consistency in this case?
- Yes! No matter of the tuples in the constraint relation e
- Every constraint is a core of the instance

tp-covering (acyclic version)

- The constraint e(X,Y) is **tp-covered** in an acyclic hypergraph if,
 - add a fresh constraint e'(X,Y) (where e' is a fresh relational symbol),
 - a core of the new instance has an acyclic hypergraph
- Intuitively the "coloring" of e(X, Y) forces the core of the new structure to deal with the ordered pair (X, Y)
 Indeed, every core must contain e'(X, Y)
- Instead, the usual notion of the core does not preserve the meaning of variables
 - this is crucial for computing solutions, but not for the decision problem

The Power of Pairwise Consistency

- The constraint e(X,Y) is **tp-covered** in an acyclic hypergraph if,
 - add a fresh constraint e'(X,Y) (where e' is a fresh relational symbol),
 - a core of the new instance has an acyclic hypergraph

Local (pairwise) consistency entails Global consistency if and only if every constraint is tp-covered in an acyclic hypergraph

tp-covering by Example

- The constraint e(X,Y) is tp-covered in an acyclic hypergraph if,
 - add a fresh constraint e'(X,Y) (where e' is a fresh relational symbol),
 - a core of the new instance has an acyclic hypergraph

tp-covering by Example

- The constraint e(X,Y) is tp-covered in an acyclic hypergraph if,
 - add a fresh constraint e'(X,Y) (where e' is a fresh relational symbol),
 - a core of the new instance has an acyclic hypergraph

tp-covering by Example

- Here pairwise consistency solves the satisfaction problem
- The structure of any core is an undirected acyclic graph

The power of Pairwise Consistency

- Here pairwise consistency solves the satisfaction problem
- The structure of any core is an undirected acyclic graph
- However, it does not entail global consistency
- There is an instance that is pairwise consistent but e(A,B) contains wrong tuples

A generalization: Local k-consistency

- Consider subproblems of k constraints
- Local k-consistency: pairwise consistency over such (kconstraints) subproblems
 Equivalent to relational k-consistency [Dechter and van Beek. TCS'97]

Local k-consistency entails Global consistency if and only if every constraint is tp-covered in a hypergraph having Generalized Hypertree width k

[Greco and Scarcello. PODS'10]

 See the appendix for a further generalization to arbitrary subproblems in the general framework of tree projections

Membership in the Core on Graph Games

The Core: $\forall S \subseteq N, x(S) \ge v(S);$ x(N) = v(N)

Consider the sentence,

over the graph where N is the set of nodes and E the set of edges :

 $proj(X, Y) \equiv X \subseteq N \land$ $\forall c, c' (Y(c, c') \to X(c) \land X(c')) \land$ $\cdots = f(Y(c) \land X(c') \land E$ $\forall c, c' (X(c) \land X(c') \land E(c, c') \to Y(c, c'))$

... it tells that Y is the set of edges covered by the nodes in X

The Core: $\forall S \subseteq N, x(S) \ge v(S);$ x(N) = v(N)

Let proj(X, Y) be the formula stating that Y is the set of edges covered by the nodes in X

Define the following weights: $w_E(c,c') = -w(c,c'); \quad w_N(c) = x_c$ 1 1 Value of the edge (negated) Value at the imputation

Membership in the Core on Graph Games

The Core:
$$\forall S \subseteq N, x(S) \ge v(S);$$

 $x(N) = v(N)$

Let proj(X, Y) be the formula stating that Y is the set of edges covered by the nodes in X

Define the following weights:
$$w_{\mathcal{E}}(c,c') = -w(c,c'); \quad w_N(c) = x_c$$

 \bigwedge
Value of the edge (negated) Value at the imputation

Find the "minimum-weight" X and Y such that proj(X, Y) holds

Outline of Part III

Applications to Optimization Problems

Application: Nash Equilibria

Application: Coalitional Games

Application: Combinatorial Auctions

Appendix: Beyond Hypertree Width

<u>Winner Determination Problem</u> • Determine the outcome that maximizes the sum of accepted bid prices

Structural Properties

Dual Hypergraph

JCAI-13

Outline of Part III

Applications to Optimization ProblemsApplication: Nash EquilibriaApplication: Coalitional GamesApplication: Combinatorial Auctions

Appendix: Beyond Hypertree Width

Going Beyond...

- Treewidth and Hypertree width are based on tree-like aggregations of subproblems that are efficiently solvable
- Image: k variables (resp. k atoms) → ||I||^k solutions (per subproblem)
- Is there some more general property that makes the number of solutions in any bag polynomial?
- YES! [Grohe & Marx '06]

Fractional Hypertree Decompositions

In a fractional hypertree decomposition of width $w,\, {\rm bags}$ of vertices are arranged in a tree structure such that

- 1. For every edge $e, \, {\rm there} \, {\rm is} \, {\rm a} \, {\rm bag} \, {\rm containing} \, {\rm the} \, {\rm vertices} \, {\rm of} \, e.$
- 2. For every vertex v, the bags containing v form a connected subtree.
- 3. A fractional edge cover of weight \boldsymbol{w} is given for each bag.

Fractional hypertree width: width of the best decomposition.

Note: fractional hypertree width \leq generalized hypertree width

[Grohe & Marx '06]

- A query may be solved efficiently, if a fractional hypertree decomposition is given
- FHDs are approximable: If the the width is ≤ w, a decomposition of width O(w³) may be computed in polynomial time [Marx '09]

More Beyond?

- A new notion: the submodular width
- Bounded submodular width is a necessary and sufficient condition for fixed-parameter tractability (under a technical complexity assumption)

[Marx '10]

Tree Projections (by Example) \mathbb{A} : $r_1(A,B,C)$ $r_2(A,F)$ $r_3(C,D)$ $r_4(D,E,F)$ $r_5(E,F,G)$ $r_6(G,H,I)$ $r_7(I,J)$ $r_8(J,K)$

Structure of the CSP

Available Views

Tree Projections (by Example)

- variables Generalized hypertree width: take all views that can be computed by joining at most k atoms (k query views)
- ٩
- Fractional hypertree width: take all views that can be computed through subproblems having fractional cover at most k (or use Marx's $O(k^3)$ approximation to have polynomially many views)

Tree Decomposition

A General Framework, but

Decide the existence of a tree projection is NP-hard

[Gottlob, Miklos, and Schwentick, JACM'09]

A General Framework, but

• Decide the existence of a tree projection is NP-hard

[Gottlob, Miklos, and Schwentick, JACM'09]

A Source of Complexity: The Core

The core of a query Q is a query Q' s.t.:

- 1. $atoms(Q') \subseteq atoms(Q)$
- 2. There is a mapping $h: var(Q) \rightarrow var(Q')$ s.t., $\forall r(X) \in atoms(Q), r(h(X)) \in atoms(Q')$
- There is no query Q" satisfying 1 and 2 and such that atoms(Q") ⊂ atoms(Q')

A Source of Complexity: The Core

The core of a query Q is a query Q' s.t.:

- 1. $atoms(Q') \subseteq atoms(Q)$
- 2. There is a mapping $h: var(Q) \rightarrow var(Q')$ s.t., $\forall r(X) \in atoms(Q), r(h(X)) \in atoms(Q')$
- 3. There is no query Q" satisfying 1 and 2 and such that $atoms(Q^{\prime\prime}) \subset atoms(Q^{\prime})$

Q Q' Example: -2 (6)

Example

 $\begin{array}{rl} Q &: & r(A,B) \wedge r(B,C) \wedge r(A,C) \wedge r(D,C) \wedge \\ & r(D,B) \wedge r(A,E) \wedge r(F,E), \end{array}$

Example

CORE is NP-hard

- Deciding whether Q' is the core of Q is NP-hard
- For instance, let 3COL be the class of all 3colourable graphs containing a triangle
- Iclearly, deciding whether G∈3COL is NP-hard
- It is easy to see that $G \!\in\! \! 3COL \Leftrightarrow K_3$ is the core of G

Enforcing Local Consistency (Acyclic)

- The followings are equivalent:
 - Local consistency solves the decision problemThere is *a core* of the query having a tree projection

[Greco & Scarcello, PODS'10]

The Precise Power of Local Consistency

• The followings are equivalent

- Local consistency solves the decision problem
- There is a core of the query having a tree projection

 $\begin{array}{ll} Q &: & r(A,B) \wedge r(B,C) \wedge r(A,C) \wedge r(D,C) \wedge \\ & r(D,B) \wedge r(A,E) \wedge r(F,E), \end{array}$

The Precise Power of Local Consistency

The followings are equivalent
 Local consistency solves the decision problem

• There is a core of the query having a tree projection

[Greco & Scarcello, CP'11]

Back on the Result

The followings are equivalent

Local consistency solves the decision problem
There is a core of the query having a tree projection

«Promise» tractability

- There is no polynomial time algorithm that
 - either solves the decision problemor disproves the promise

The followings are equivalent
 Local consistency entails «views containing variables O are correct»
 The set of variables O is tp-covered in a tree projection

Thank you!
